CNN for image classification

Pre-trained model

- <https://github.com/ShiqiYu/SimpleCNNbyCPP>

Model

- 3 Convolutional layers (Conv+BN+ReLU)
- 2 MaxPool
- 1 Full connected layer

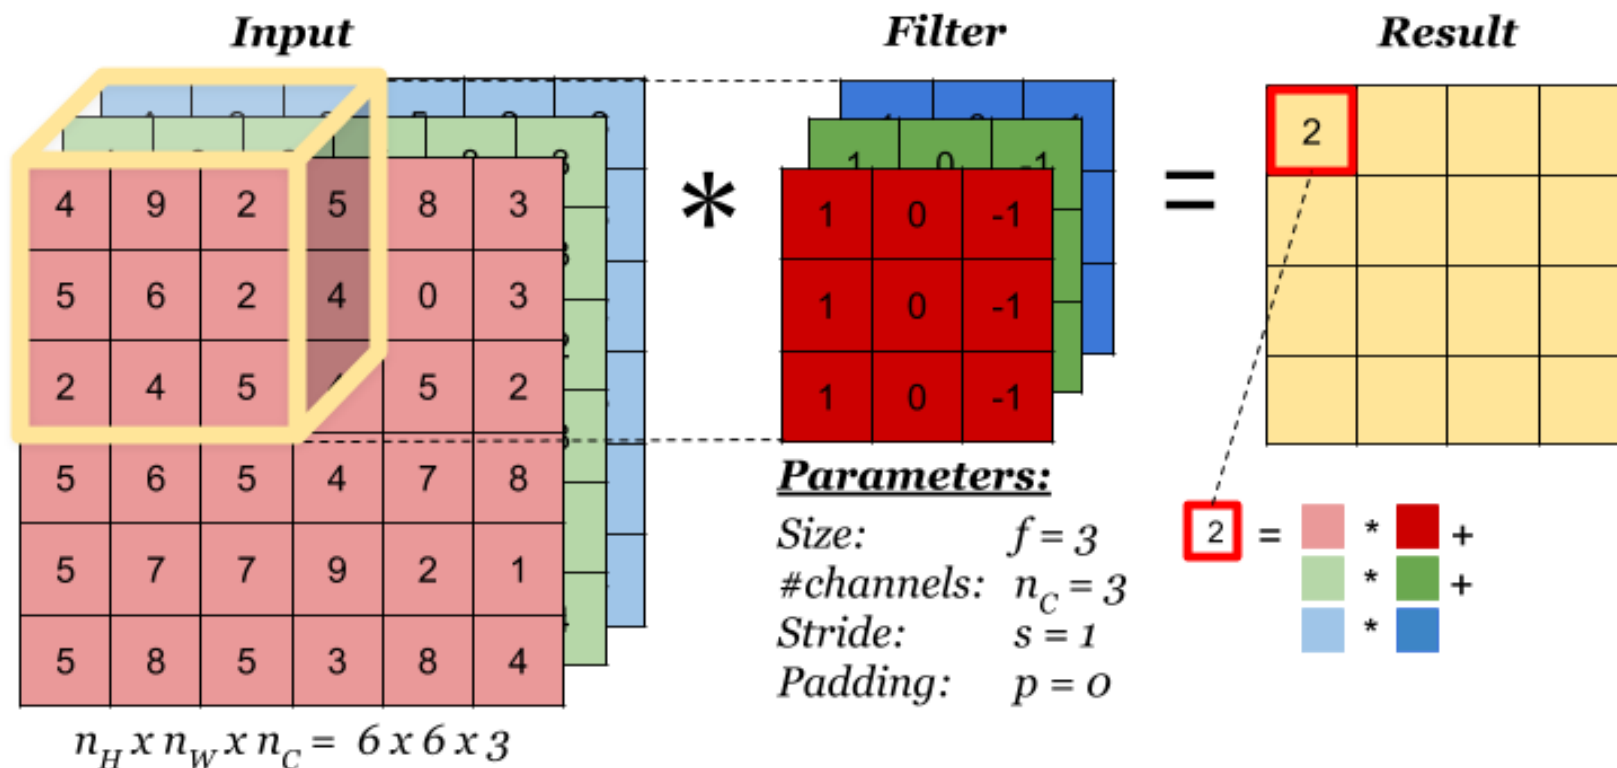

```
self.backbone = nn.Sequential(
    ConvBNReLU(3, 16, 3, 2, 1),      # downsampled by 2, 128 -> 64
    nn.MaxPool2d(2, 2),              # downsampled by 2, 64 -> 32
    ConvBNReLU(16, 32, 3, 1),        # keep
    nn.MaxPool2d(2, 2),              # downsampled by 2, 32 -> 16
    ConvBNReLU(32, 32, 3, 2, 1)      # downsampled by 2, 16 -> 8
)

self.classifier = nn.Sequential(
    nn.Linear(in_features=32*8*8,
              out_features=num_cls,
              bias=True)
)
```

conv

- Multiple filters (kernels) can create multiple output channels

conv

0	0	0	0	0	0	...
0	156	155	156	158	158	...
0	153	154	157	159	159	...
0	149	151	155	158	159	...

+

+ 1 = -25

Bias = 1

Output

-25				...
				...
				...
				...
...

conv

- A convolutional kernel create a channel in the output data.

Batch normalization

- The BN layers have been merged into conv layers

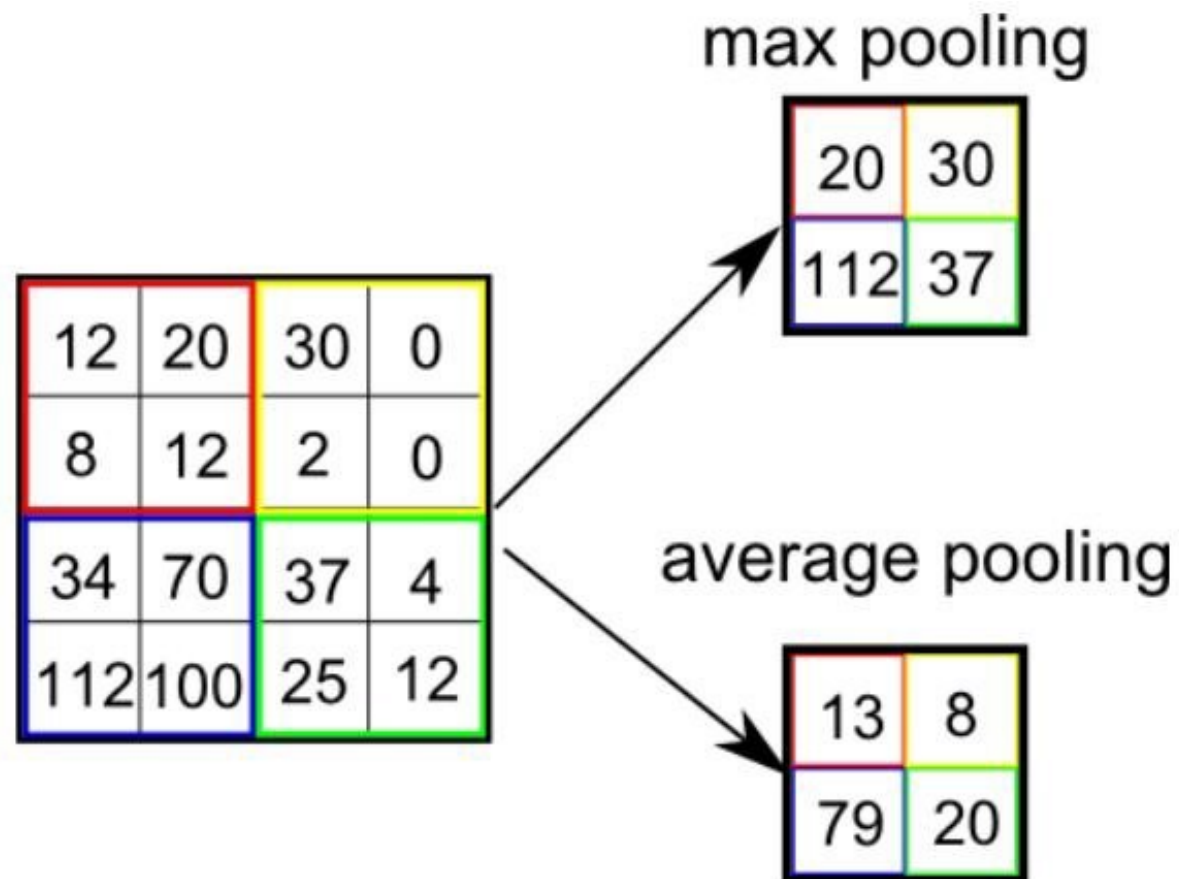

ReLU: Rectified Linear Unit

```
if (x < 0)  
    x = 0;
```

max pooling

- For each channel

- If the input is $C \times H \times W$, the output will be $C \times H/2 \times W/2$

Flatten

- The data blob is flattened into a 2048-length vector from 32x8x8

FC: Fully-Connected Layer

- If the input is L and the output is N (2 in the model, 4 in left figure), the size of weights is $N \times L$ (2×2048 in the model)

$$\text{output}_{2 \times 1} = \text{weight}_{2 \times 2048} * \text{input}_{2048 \times 1} + \text{bias}_{2 \times 1}$$

Softmax

- To output the confidence vector (n=2 in the model)

for $x \in \mathbb{R}^n$

$$p_i = \frac{e^{x_i}}{\sum_{j=1}^n e^{x_j}}$$

$$p = \begin{pmatrix} p_1 \\ \vdots \\ p_n \end{pmatrix}$$

CNN Explainer

- <https://poloclub.github.io/cnn-explainer/>

The slides are based on the book <Stephen Prata, C++ Primer Plus, 6th Edition, Addison-Wesley Professional, 2011>

Exceptions

Rudimentary Options

- An example: **harmonic** mean of two numbers

$$2.0 \times x \times y / (x + y)$$

- Calling **abort()**: **program example error1.cpp**
 - Send a **message** such as "abnormal program termination" to the standard error stream and **terminate** the program
 - **Return** an implementation-dependent value that indicates failure to the **operating** system
- Returning an **error code**: **program error2.cpp**
 - **Return** values to **indicate** a problem
 - We have used it in the previous examples

Throw-Catch Mechanism

- An **exceptional** circumstance arises while a program is **running**
- Exception mechanism provide a way to **transfer** control from one part of a program to another
 - Throwing an exception
 - ✓ **throw** keyword indicates the **throwing** of an exception
 - ✓ A throw statement, in essence, is a **jump** (other jump operators??)
 - Catching an exception with a handler
 - ✓ **catch** keyword indicates the **catching** of an exception
 - ✓ Followed by a **type declaration** that indicates the **type of exception**
 - Using a try block
 - ✓ A **try** block identifies a block of code for which **particular exceptions** will be activated
 - ✓ Followed by **one or more** catch blocks
- See program example `error3.cpp`

Throw-Catch Mechanism

- Can we use more complex **types**? YES!
- Using objects as exceptions
 - Advantage: use **different exception types** to distinguish among **different functions and situations** that produce exceptions
 - An object can **carry** information with it, and you can use this information to help identify the conditions that caused the exception to be thrown
 - A catch block could use that information to **decide** which course of action to pursue
- See program example **error4.cpp**
 - Geometric and harmonic means

More Exception Features of Throw-Catch Mechanism

- Differences to the normal function
 - One difference
 - ✓ A return statement: **transfer** execution to the **calling** function
 - ✓ A throw: **transfer** execution to the **first** function having a **try-catch**
 - Second difference
 - ✓ The compiler always creates a **copy** when throwing an exception
- The **exception** class
 - Define an exception class that C++ uses as a **base** class
 - One **virtual** member function is named **what()**, and it returns a string

```
#include <exception>
class bad_hmean : public std::exception
{
public:
    const char * what() { return "bad arguments to hmean()"; }

    ...
};
```

More Exception Features

- The **stdexcept** exception classes
 - The **stdexcept** header file defines **several** more exception classes
 - **logic_error** and **runtime_error** classes
 - ✓ **logic_error family**: **domain_error**, **invalid_argument**, **length_error**, **out_of_bounds**
 - ✓ **runtime_error family**: **range_error**, **overflow_error**, **underflow_error**

Class **std::logic_error**

```
namespace std {  
    class logic_error : public exception {  
    public:  
        explicit logic_error(const string& what_arg);  
        explicit logic_error(const char* what_arg);  
    };  
}
```

Class **std::domain_error**

```
namespace std {  
    class domain_error : public logic_error {  
    public:  
        explicit domain_error(const string& what_arg);  
        explicit domain_error(const char* what_arg);  
    };  
}
```

```
namespace std {  
    class logic_error;  
    class domain_error;  
    class invalid_argument;  
    class length_error;  
    class out_of_range;  
    class runtime_error;  
    class range_error;  
    class overflow_error;  
    class underflow_error;  
}
```

More Exception Features

- The `bad_alloc` exception and `new`
 - Have `new` throw a `bad_alloc` exception
 - `new` returned a null pointer when it couldn't allocate the memory
- See program example `newexcp.cpp`
